Wagyu

2014

Introduction

Information has been obtained from Logix as on 31/12/2014.

Birth Weight, Pre-wean Weight, Weaning Weight, 12 Month Weight, 18 Month Weight, Cow Weight at Calving, Cow Weight at Weaning of Calf, Age at First Calving (AFC) and Inter-calving Period (ICP) are measured on the farm by the farmer himself. The environment in which these traits are measured therefore varies between herds. Environmental factors include veld type, climate, management practices, terrain and available feed. Traits such as Height, Length, Skin Thickness, Scrotal Circumference, Final Weight and Real-Time Ultrasound (RTU) measurements are taken by the technical advisor allocated to a particular area at the end of the on-farm testing. In 2014, 19 breeds took part in on-farm testing.

Centralised testing takes place at various centralised testing centres located through-out the country. The animals are individually fed a standardised ration and are compared within the same environment. There is an adaptation period of 28 days, followed by a test length of 84 days. Body weights and feed intake are measured regularly, and Height, Length, Skin Thickness, Scrotal Circumference, Final Weight and RTU measurements are taken at the end of the test. Individual feed intake measurements allow for the calculation of feed conversion ratio (FCR), a measure of feed efficiency. In 2014, 17 breeds took part in centralised testing.

Percentages and average values may be misleading when there are few herds or animals, and is not necessarily a true representation of the breed. For example, a participation percentage of 80 on a breed with 1000 is a good representation of the breed, as this includes 800 herds, but on a breed with 5 herds it is not, as this only includes 4 herds.

Be careful when comparing the performance of breeds with each other. The values presented here are dependent on genetic merit and environmental factors, and the breeding objectives may differ between breeds.

Pie charts are presented for herds registered at SA Stud Book and herds in Logix Beef. All breeds with less than 20 herds are grouped as “other”.

Averages that appear on the bottom of the tables are corrected averages – total value of measurements divided by the total number of animals measured. In other words, it is not the total averages per breed divided by the number of breeds. This is to take into account that all breeds do not have the same number of animals and therefore cannot have equal contributions to the average. Weight averages for males and females are adjusted for age.

The gender of the animals presented in the tables is both indicated in the title and with the use of a background picture, where:

= Female

= Male

* Averages based on few measurements are not meaningful representations of the breed and should be interpreted with caution.

Cow weights are the weights of the cow at calving and weaning of her calf respectively.

Weights are adjusted for age.
